Troubleshooting guidelines: Turbochargers - INSTALLATION STEPS

1 Determine the cause of the breakdown

Before fitting a new turbocharger, you must determine what has caused the breakdown of the old turbo. The problem, that caused the breakdown of the turbo, will likely also be able to damage the new turbo.

2 Check intake

Check the intake system for leaks— check pipes – hoses for bends or dents that could limit the air supply. Any leaves or dirt must be cleared out. If in doubt if the air filter has been changed recently – replace it – if there is damage to the compressor wheel, you must investigate from where the object has entered – check that all parts are complete up to the air filter. Charge air hoses must also be checked for leaks, bends, and oil. Also, check and if needed clean or replace the intercooler.

3 Check fuel system

Check the fuel system – if the build up of soot is excessive in the intake manifold– this could be a sign of problems with the fuel system – check the air mass sensor, EGR, injection, or possible oil consumption from the engine.

4 Check exhaust

Check the DPF or catalyst for clogging. Check manifold and exhaust for tightness. Check the old turbine wheel for damage, that could be caused by debris from the engine or EGR valve, if damaged you need to find the problem, that caused it.

5 Check oiling

Replace the oil feed pipe, and clean or replace the oil return pipe. Check that the crank ventilation is working properly. Check the old oil for excessive soot build up – check the oil pan for contamination with soot or metal debris from wear of crank or rod bearings. If problems are found here, they need to be taken care of before the turbo is replaced.

6 Check actuator

Check the vacuum lines to the turbo for tightness and bends, that could prevent the vacuum from reaching the actuator. If the actuator is electric – please check the connector.

7 Change oil

Before starting up the new turbo, change the oil and filter on the engine.

8 Fit new gaskets, pre oil turbo

When installing the new turbo – make sure to use the new gaskets – observe, that some gaskets may be possible to fit in a wrong position, which will allow the gasket to partly cover the exhaust intake of the turbo, so make sure to fit in the correct position. Avoid using any liquid sealant for the oil supply – this can close the oil supply to the turbo. Make sure to use the correct torque on all parts, when reassembling, and please use the supplied start-up oil to add to the oil intake before cranking the engine. Spin the axle carefully by hand to distribute the oil. When starting up, disconnect the ignition, and engage the starter for a while to build up oil pressure. When connecting the ignition and starting up – please allow the engine to idle for a couple of minutes.

Troubleshooting guidelines: Turbochargers - POSSIBLE ERRORS

Problem Oil leak	Cause	How to identify	Why the problem occurs	Solution	Preventive actions
Oil leak	Crank ventilation not working	When lifting the dipstick – check if pressure is released	Increased pressure from the crank case is preventing oil return from the turbo	Replace PCV	Check before fitting a new turbo, that the PCV is ok
	Oil return line blocked by use of liquid sealant	Unscrew the oil return line, check if oil is flowing back	Liquid sealant is blocking the flow of oil	Avoid using sealant	Clean surfaces, and use only gaskets to seal
Oil leak	Increased pressure in crankcase caused by engine wear	PCV working, but pressure is high	Blow by is causing too high pressure in crank case	Replace valve guides or pistons/rings as needed	Never exceed service intervals. Check for pressure in crankcase before turbo replacement
Lack of power	Lack of intake air	Clogged air filter/ damaged hoses	Air filter not changed, hoses pinched of during installation	Replace filter or hoses	Fit new air filter, inspect hoses
Lack of power	Lack of charge air	Leak between turbo and intake manifold	Wear on parts	Replace leaking parts	Check tightness before installation
Lack of power	Exhaust leaks in manifold or joints	Exhaust leaking into engine bay	Cracks in manifold, bolts not torqued	Replace manifold, torque bolts down, and replace gaskets	Check for tightness before installation, use correct torque
III					

Troubleshooting guidelines: Turbochargers - POSSIBLE ERRORS

Problem	Cause	How to identify	Why the problem occurs	Solution	Preventive actions
Lack of power	Blockage in DPF/ Catalyst	Black smoke, engine light on	Soot build up in exhaust	Clean/replace	Examine why the soot builds up – injection, EGR, airmass, etc.
Lack of power	Vacuum lines not tight, or bent	Actuator is not moving, or not moving enough	Lines worn or bent	Replace vacuum line	Before replacement, check tightness of lines, if they cannot hold vacuum, replace
Lack of power	Vacuum solenoid valve not working	The lines are tight, but vacuum doesn't reach the actuator	The valve is worn out	Replace the vacuum valve	Before replacement of the turbo, check, that vacuum is present at the actuator Check fuel system to avoid buildup of soot
Lack of power	EGR valve stuck open	If you unplug the EGR valve at some revs, Air- mass doesn't change on diagnostic tester Check with diagnostic tester, that the expected value at idle is ok	Due to soot, EGR valve is stuck in open position MAP or airmass sensor are failing	Replace EGR valve Replace sensor	Check Sensors before replacing the turbo
Lack of power	Intake throttle not working correctly	Check that the throttle moves freely	Throttle failing, or build up of soot	Replace or clean throttle	Check throttle before replacing the turbo

Troubleshooting guidelines: Turbochargers - POSSIBLE ERRORS

Problem	Cause	How to identify	Why the problem occurs	Solution	Preventive actions
Lack of power	Intake manifold contaminated	Visual inspection	Buildup of soot	Replace or clean	Check fuel system to avoid buildup of soot
Black smoke	Airfilter contaminated	Visual inspection	Lack of service	Replace	If in doubt of when the filter was last replaced, replace it at turbo re-placement
Black smoke	Air intake hose collapsed or restricted	Visual inspection	Damaged when working on other items	Remove restriction or replace hose	Visual inspection before replacement of turbo
Black smoke	Leak between compressor and intake	Inspection of hoses, intercooler, gaskets, manifold	Wear of parts, damaged parts	Replace or tighten clamps/gaskets/hoses as needed	See/hear/feel for any leaks
Black smoke	Intake manifold contaminated	Visual inspection	Buildup of soot	Replace or clean	Check fuel system to avoid buildup of soot
Black smoke	Damage to compressor wheels	Visual inspection	Object from airside damaged the wheel	Inspect intake – find out where the object came from and fix the problem, and install new turbo	Inspect all intake parts at replacement of turbo
					V

Troubleshooting guidelines: Turbochargers - POSSIBLE ERRORS

Problem	Cause	How to identify	Why the problem occurs	Solution	Preventive actions
Black smoke	Problem in fuel injectors or pump(S)	Diagnostic tester	Parts worn	Replace needed parts	Check the fuel system before fitting a new turbo
Black smoke	Problem with MAP or Airmass sensor	Check with diagnostic tester, that the expected value at idle is ok	MAP or airmass sensor are failing	Replace sensor	Check Sensors before replacing the turbo
Black smoke	Blockage in DPF/ Catalyst	Black smoke, engine light on	Soot build up in exhaust	Clean/replace	Examine why the soot builds up – injection, EGR, airmass, etc.
White/Blueish smoke	Engine oil consumption too high	Check oil consumption	Wear on pistons/rings, liners valvetrain, gaskets	Repair problem as needed	Check oil consumption before fitting a new turbo
White/Blueish smoke	Crank ventilation not working	When lifting the dipstick – check if pressure is released	Increased pressure from the crank case is preventing oil return from the turbo, and increasing consumption	Replace PCV	Check before fitting a new turbo, that the PCV is ok
White/Blueish smoke	Leak between compressor and intake	Inspection of hoses, intercooler, gaskets, manifold	Wear of parts, damaged parts	Replace or tighten clamps/gaskets/hoses as needed	See/hear/feel for any leaks
					VI

Troubleshooting guidelines: Turbochargers - POSSIBLE ERRORS

Problem	Cause	How to identify	Why the problem occurs	Solution	Preventive actions
White/Blueish smoke	Lack of intake air	Clogged airfilter/ damaged hoses	Airfilter not changed, hoses pinched of during installation	Replace filter or hoses	Fit new airfilter, inspect hoses
White/Blueish smoke	Oil return line blocked by use of liquid sealant	Unscrew the oil return line, check if oil is flow- ing back	Liquid sealant is blocking the flow of oil	Avoid using sealant	Clean surfaces, and use only gaskets to seal
White/Blueish smoke	Residue from the old turbo	If the old turbo was leaking oil	Oil from the old turbo left in exhaust	If the amount of oil is not excessive, let it burn off	If the amount is exces- sive at disassembly, wipe it off as far as possible
Noise	Whistling noise	Compressor wheel damaged by foreign object	Visual inspection	Replace turbo	Before fitting a new turbo, make sure, that air ducts, and all in- take parts are in good shape
Noise	Leaks from intake, charge side or exhaust	Check the intake hose, charge hoses, inter- cooler, manifold, turbo & exhaust for leaks	Wear on parts, or incorrect gaskets or torque has been used	Tighten screws or re- place needed gaskets, hoses or cracked mani- fold or exhaust parts	Inspect intake, charge hoses and exhaust parts before fitting a new turbo
Noise	Metallic noise – com- pressor- or turbine- wheel damaged by foreign object	Visual inspection	Parts from intake or engine has entered the turbo and damaged the wheel	Identify where the part has come from and correct the problem, and replace the turbo	Inspect intake well before installing a new turbo. If the old turbo has damaged turbine or compressor wheel, clarify why

REPAIR OF A DAMAGED TURBOCHARGER

1. INTRODUCTION

Most failures of the turbocharger are due to problems occurring outside the device. If the turbocharger is faulty, apart from its repair or replacement, it is imperative to determine and eliminate the cause of failure to prevent its recurrence.

Figure 1 shows damage to the turbocharger caused by the entry of a foreign object into its housing. The foreign object has damaged the compressor wheel at the front i.e. inlet, leading to a partial fracture of its blades. Blade damage causes rotor imbalance as well as rapid wear to the bearings and seal rings. This results in increased lubricating oil consumption, power loss and black or white smoke coming from the exhaust pipe. Also, these problems are often accompanied by a squeaking sound, which clearly indicates

turbocharger malfunction. Foreign objects may enter the inlet manifold: due to a damaged air filter, due to holes or cracks in the air hoses or worn-out hose clamps, or if the entire air supply system has not been properly cleaned during the previous servicing of the turbocharger [2].

Figure 1. Compressor wheel damaged by a foreign object

Figure 2. Compressor wheel damaged by a large foreign object

Before reinstalling the turbocharger, it is necessary to determine the routes of foreign object ingestion into the turbocharger in order to prevent recurring impact damage. To this end, the inlet manifold hoses should be inspected and washed, the hose clamps and the air filter should be checked for foreign objects and replaced as required. Otherwise, the turbocharger will suffer the same failure.

Figure 3. Compressor wheel damaged by dirt

Figure 4. Rotor damaged by foreign objects with soot build-up

Figure 5. Rotor damaged by foreign objects

2.DAMAGE TO THE TURBOCHARGER

After disassembly of the turbocharger, damage typical of a partial or complete blockage in the exhaust pipe has been identified. This type of blockage in the pipe causes a high exhaust gas pressure in the turbine housing. As exhaust gases cannot exit the engine freely, they push the turbocharger rotor forward to the compressor side.

Therefore, on the front side of the turbine wheel, there are clearly visible marks of its unallowable wear against the flame guard, leading to turbocharger oil leaks. This failure is caused by a faulty (blocked) engine brake (a faulty brake cylinder or a clogged butterfly valve shaft) or by a foreign object blocking the exhaust pipe.

Before reinstalling the turbocharger, the cause of the failure (in this case, the faulty engine brake and/or blocked exhaust pipes) must be eliminated.

Figure 6. Damage to the turbocharger rotor due to blockage in the exhaust pipe

Wet oil found at the turbine inlet is a characteristic sign of a forced oil leak. The compressor housing is soiled with oil at the

inlet; therefore, as the turbocharger sucks in air, the oil can only come from the breather. The inspection of the intake hose clearly shows that the leaking oil is working its way from the breather towards the turbocharger. Due to an engine problem, pressure builds up in the engine crankcase. Increased pressure raises the oil level in the crankcase, resulting in fresh oil at the breather. As the turbocharger is connected to the engine crankcase through the oil return pipe, the seal rings become overloaded with pressurised oil, which forces its way through them, eventually causing physical damage to them, resulting in the need for repair. In such failures, oil consumption is always higher due to an engine problem than due to a problem in the turbocharger. Therefore, this problem (increased oil consumption) cannot be solved only by turbocharger repair.

Figure 7. Effect of oil pressure in the engine crankcase on the turbocharger

The increased pressure in the crankcase is due to a variety of reasons:

1. The breather is clogged. The intake hose on the turbocharger is dry.
2. The oil return line which allows oil to drain from the turbocharger to the crankcase is bent, clogged, with a restricted flow. Normally, it must have an appropriate oil drain angle (± 15 degrees from the vertical).
3. The air filter is dirty.
4. The internal pressure in the engine is too high, due to the wear of engine

parts and assemblies (worn-out piston rings, cylinder liners and other parts of the engine).

The excessive oil pressure problem in the crankcase must be fixed before reinstalling a new or repaired turbocharger, since otherwise the problem will not be permanently solved.

After the core assembly of the turbocharger has been dismantled, high wear rates of the sliding surfaces of the bearings and the shaft have been found. Wear marks i.e. furrows in characteristic places, due to dirt in the lubricating oil, are clearly visible. The oil is contaminated with combustion by-products and shavings of engine parts. Depending on the degree of oil contamination, the gap between the bearings and the shaft increases over time, causing wear to the seal rings, imbalance of the turbocharger rotating assembly and even striking of the turbine and compressor wheel blades against the housing. The turbocharger consumes oil, the engine has no power, and black or white smoke appears at the exhaust outlet. When installing the hose with oil supply and return fittings, sealants must not be used because only original gaskets are permitted.

Figure 8. Radial bearings damaged by dirty oil

When performing major repairs of automobile engines, such as overhaul, leftover shavings may get into the oil and cause wear.

Since the turbine rotor spins up to 50 times faster than other shafts on the engine, turbo wear is much higher and faster. After the overhaul, the engine crankcase should be thoroughly washed. Before reinstalling the turbocharger, the cause of the failure must be eliminated. It is necessary to replace both the oil and the oil filter and clean the engine

crankcase to prevent recurring problems.

Figure 9. Damage to the turbocharger shaft caused by dirty oil

Figure 10. Damage to the turbocharger shaft due to lack of lubrication

In older types of turbochargers which do not have VSG valves, failure is caused by disruption in the fuel combustion system, due to which exhaust gas pressure and temperature exceed predetermined values. At high rotational speeds, the rotor material undergoes internal stress, which leads to blade fracture, and the turbocharger bearings cannot withstand such loads, resulting in frequent rotor impeller cracks. Turbochargers equipped with VSG valves are designed to operate at higher rotational speeds compared to the turbochargers without VSG valves. When the exhaust gas pressure in the turbocharger reaches the critical, maximum allowable value, the role of the VSG valve is to direct the exhaust gas flow out of the rotating zone of the rotor, thus reducing its rotational speed.

In the new generation of turbochargers having variable geometries, in addition to the abovementioned role, the electromagnetic valve regulates both the amount and pressure of exhaust gases during the operation. When the VSG valve is damaged or unprofessionally adjusted, the turbocharger rotor rotates at a rotational speed higher than the maximum limit. Therefore, the engine consumes more oil and loses power, and the turbocharger produces a characteristic squeaking sound. Often, the turbocharger rotor breaks due to internal load. In variable geometry turbochargers, there is damage to the rotor, the variable geometry and the central housing, and the only solution is to replace the turbocharger with a new one.

Figure 11. Typical fracture of the turbocharger impeller

Figure 12. Effect of high temperature on the turbocharger rotor

Figure 13. Cracks in the turbine housing due to a high exhaust gas temperature

3.REPAIR OF THE TURBOCHARGER

In practice, as a rule, successful repair of a turbine is possible only if its housing is not mechanically damaged. Repair generally involves replacement of the shaft coupled with the propellers, bearings and all seal components. This is the primary and cheapest ~~when~~ repairing the turbine, all its components are disassembled. They are usually rather dirty, which does not necessarily mean that they are damaged. However, soot build-up can block the stator blades. This is the cheapest intervention as there is no need for replacement of the turbine components. [1]

Figure 14. Turbine disassembly [1]

Before repair, all dismantled parts are thoroughly cleaned using a special liquid solvent, or petroleum, or a certain amount of a degreasing agent. After drying, they are subjected to sandblasting, which involves smoothing of large rough surfaces occurring due to mechanical operation, which may subsequently lead to undesirable effects. Since blasting is performed by quartz crystals of small grain size, all parts should be additionally washed in a solvent additive or in petroleum

after the process. Also, they should be dried either with a soft cloth or simply under compressed air. It is only after these detailed cleaning and drying operations that certified service providers can determine the degree of repair needed.

Figure 15. Cleaning, degreasing and sandblasting [1]

Turbine failure is generally determined by visual inspection. The shaft with the blades on both sides is the most visible and, practically, the key part of the turbine. The blades on the side through which clean air passes are the most vulnerable. If any particle of dirt enters this area, at least one vane will become damaged, which will automatically lead to mass imbalance and unbalanced rotation. Such rotation will, by all means, cause damage to the nearest bearing in no time. If, for example, a stone or a piece of glass or some other hard object gets into this area, the entire section will be destroyed and the blades

broken. This damage will probably result in a complete loss of symmetry in the shaft. Similarly, the drive blades can suffer damage due to poor combustion and extremely high temperatures. The blades in such an operating environment erode over time, which reduces the operating life of the turbine.

Another reason for turbine damage is poor lubrication. The turbine shaft is lubricated with oil from the engine, and the oil also serves as a coolant. If for any reason lack of lubrication or oil starvation occurs, the bearings (bronze rings) will be the first to suffer damage. Also, due to increased temperatures and loss of balance during rotation, seal rings will become permanently damaged.

Figure 16. The most common types of damage [1]

Even in prolonged contact with lubricating oil, these rings will not be able to retain hot oil under pressure, and over time the oil will leave the lubrication area through them. Although damaged, the turbine can be reconditioned. Any reconditioning operation after turbine disassembly involves the replacement of seal rings, bronze bearings and rubber seals. Well-equipped service providers use kits including the replacement components required during turbine disassembly. The turbine contains the so-called seal plate or housing cover, which is generally not replaced. In variable geometry turbines, the stator section should also be

replaced in major overhauls. Undamaged components are reinstalled in the housing in reverse order.

Figure 17. Reconditioning of turbine parts [1]

When reinstalling the existing shaft and blades or installing new components, the assembly should be additionally balanced. It is only after this operation that the turbine can

be assembled. Balancing is among the most sensitive processes during turbine reconditioning. It is performed only by trained service providers. Excess removal of the material during the balancing operation may cause permanent damage to the turbine.

Figure 18. Balancing of the shaft and blades [1]

4. CONCLUSION

Repair primarily serves to restore the operating performance of machine parts suffering surface damage (wear) and fracture. Rather than being disposed of as waste, worn-out and broken parts are repaired and reinstalled in mechanical structures instead of new spare parts. Repair has been widely applied for the following reasons: high competitiveness, struggle to make the maximum possible profit, and economic, energy-based and ecological crises. As repair of mechanical parts and structures requires expert knowledge in different fields (knowledge of materials, types of damage, mechanical engineering calculations, etc.), it cannot be performed by a single person, but by a well-balanced team of experts.
